Post-harvest agriculture in a changing climate

Climate change will continue to exert its influence not only on crop production, but also on the increasingly valuable harvest. This article shares highlights from the author’s recent review of post-harvest agriculture in changing climates. It has a particular focus on durable cereal crops in the smallholder context of sub-Saharan Africa, revealing important insights into the bearing of post-harvest agriculture on global concerns such as food security.

Global warming is bringing complex and diverse climate change and impacts in sub-Saharan Africa (SSA; see Box on page 13). The economies of, and livelihoods in, many SSA countries are based on smallholder rain-fed agriculture. Whilst agricultural production in many higher-latitude countries is initially likely to benefit from moderate global warming, in tropical regions where crops are already close to critical environmental thresholds, crop yields and areas suitable for growing them will decline. Studies suggest that by 2080, countries such as Tanzania and Zimbabwe could lose up to 30 per cent of their 1990 cereal yields (Parry et al., 2004). Declining yields are likely to trigger further agricultural expansion, deforestation, greenhouse gas (GHG) emissions and subsequently global warming.

However, climatic change is just one stressor among many complex, interacting and dynamic factors that influence smallholder farming households in SSA. Other factors include: population growth, urbanisation, education, health, especially HIV and Aids, financial service provision and market changes. Vulnerability to climate change and adaptive capacity is determined by a similarly wide combination of interacting socio-ecological factors.

### Post-harvest systems

Post-harvest systems are diverse, reflecting the varied nature of the people, place, focal crop or product and the different activity stages involved. Post-harvest systems are influenced by the activities and interactions of many different players. An agricultural innovation systems perspective provides an analytical framework with which to examine technological and institutional change in post-harvest systems; identifying the players and factors affecting demand for, and use of, existing and new post-harvest and climate change knowledge.

### Food security and post-harvest agriculture

Most cereals consumed in SSA are produced by smallholders, with commercial imports accounting for roughly 25 per cent of the cereal consumption in the region and food aid for about 5 per cent. However, post-harvest losses of cereal grains in SSA are estimated to reach nearly four billion US dollars annually, which in cash terms, equates...
Anticipated climatic changes in sub-Saharan Africa (SSA)

Projections suggest that by the year 2030, temperatures across SSA will have risen by about 1 °C compared to those of 1980–1999 (Lobell et al., 2008). Additionally, southern Africa is likely to experience a 10 per cent rainfall decrease and more frequent drought, while East Africa is expected to see rainfall increases in the north and decreases in the south. Increasing occurrences of high rainfall events and flooding are also anticipated (Christensen et al., 2007).

to wasting 15 per cent of SSA’s annual cereal production (World Bank et al., 2011). As yields are expected to decline and the value of harvested and traded commodities subsequently increases, the cost of not reducing these post-harvest losses also increases. Furthermore, in this scenario, where extra food has to be produced to compensate for losses due to ineffective post-harvest management, this is a waste of valuable resources. With Africa’s population projected to double to two billion people by 2050, and living standards and populations elsewhere also increasing, estimates suggest that global food production will need to increase by 70 per cent. Under a scenario of continuing high population growth and regional disparities in income, an additional 550 million people globally could be at risk of climate-related hunger by 2080, with 65 per cent of this increase occurring in Africa (Parry et al., 2009). There are key post-harvest elements of food availability, stability, access and utilisation. For example, maintaining high quality and sufficient stocks of stored grain enables a household (or a nation) to provide itself with a nutritional and safe supply of food until the next harvest. Given that the market value of grain typically increases up until the next harvest, grain stocks also provide a market-linked asset, part of which can be sold if needed to cover income shocks or emergencies.

Factors influencing the adaptive capacity of post-harvest systems

The successful application of post-harvest technical solutions is depend-

Post-harvest impacts of climate change

Five key climate change trends affecting different parts of SSA were identified:

- a general increase in temperature;
- more frequent occurrence of dry spells and droughts;
- more frequent occurrence of high winds, storms, heavy precipitation events and flooding;
- more erratic rainfall;
- increased rainfall amount and/or duration.

These climate change trends are unlikely to occur in isolation from each other or other drivers of change.

The potential impacts of each of these climate change trends on the different post-harvest activities, assets (human, natural, physical, social and financial) and human well-being outcomes (food security, social, financial and economic) were identified. An example of this analysis for the potential impacts of a general increase in temperature on the drying, pest management and storage activity stages, and selected assets and well-being outcomes is given in the Table on page 14.

Climate-smart post-harvest agricultural adaptation opportunities

- Growing and/or storing crops and varieties which are less susceptible to post-harvest pest attack;
- Prompt harvesting;
- Adequate and protected drying;
- Maintenance of the physical storage structures;
- Careful store cleaning and hygiene;
- Accurate estimation of food stock requirements;
- Protection and monitoring of grain to be stored for more than three months;
- Use of low GHG emission food preparation methods;
- Understanding and application of basic food safety principles;
- Increasing farmer access to market information and transport options;
- Use of early warning seasonal forecasts to project how the climatic conditions might impact on food storage or marketing strategies;
- Use of more water, energy and resource efficient processing, packaging and transport operations;
- Ensuring plant breeders evaluate post-harvest as well as pre-harvest crop characteristics; and
- Helping farmers to learn from others’ and their own experiments.
ent on a well-functioning agricultural innovation system, which through experiential co-learning practice can overcome institutional constraints which are preventing the scaling out and up of post-harvest products and processes. However, across SSA, there is a desperate lack of skilled post-harvest service providers at all levels. As well as the post-harvest skills, understanding is needed of the futility of ‘one-size-fits-all’ solutions and the importance of responsive client-focused services which support experiential learning processes to build the adaptive capacity of smallholder farmers to deal with increasingly uncertain futures. Post-harvest aspects are under-represented in most agricultural curricula. Peer learning is stifled by the very private nature of activities such as grain storage practices which usually occur behind closed doors. Additional knowledge gaps exist as regards understanding post-harvest gender roles. The lack of investment in post-harvest compared to pre-harvest agricultural development, research and policy activities only accentuates the problems of getting post-harvest knowledge into use. Perhaps climate change impacts and shocks will gradually draw attention to the crucial role that post-harvest agricultural adaptation can play in strengthening livelihoods, attracting support and developing skills for getting the many ‘no-regrets’ climate-smart post-harvest adaptation opportunities into use at scale.
